## What is HTML?

### Overview

HTML (HyperText Markup Language) is the standard markup language used to create and structure web pages and applications. It is interpreted by web browsers to render text, images, and other multimedia elements.

### Key Points

- Markup Language: Uses a system of tags to annotate text, defining structure rather than programming logic.
- HyperText: Refers to links (hyperlinks) connecting web pages to one another.
- Elements and Tags: Composed of tags enclosed in angle brackets (e.g., `<p>`, `<div>`), usually appearing in opening and closing pairs.
- DOM Generation: Browsers parse HTML to build the Document Object Model (DOM), representing the page structure.

### Important Facts

- Developed by Tim Berners-Lee in 1991.
- Current standard is HTML5, maintained by the World Wide Web Consortium (W3C) and WHATWG.
- Not a programming language; it lacks conditional statements, loops, or computational logic.
- Case-insensitive for tag names, though lowercase is the modern web standard.

### Exam Focus

- Core Role: Defines the structure of a webpage, while CSS handles presentation and JavaScript handles behavior.

- Semantic HTML: Using tags that convey meaning (e.g., <article>, <header>, <footer>) rather than purely visual tags (e.g., <b>, <i>) for better accessibility and SEO.
- Boilerplate Structure: Standard documents require declarations like <!DOCTYPE html>, <html>, <head>, and <body>.

## Quick Revision

- Stands for HyperText Markup Language.
- Used for web page structure, not logic.
- HTML5 is the current standard.
- Uses tags and attributes to define content.
